

Ecosystem analysis and scenarios in CISO Assistant

✓ Goal: Workshop 3 and the start of Workshop 4, in the tool

Session objectives

By the end of this lab:

- **Complete** the MERIDIAN group's EBIOS RM study with its ecosystem, entered as stakeholders in CISO Assistant
- **Rate** the dangerousness of each stakeholder on the tool's criteria and read the criticality it computes
- **Create** at least two strategic scenarios attached to the retained risk origin / target objective pairs, with their attack paths

- **Begin** Workshop 4 by breaking an attack path down into an operational scenario rated in likelihood

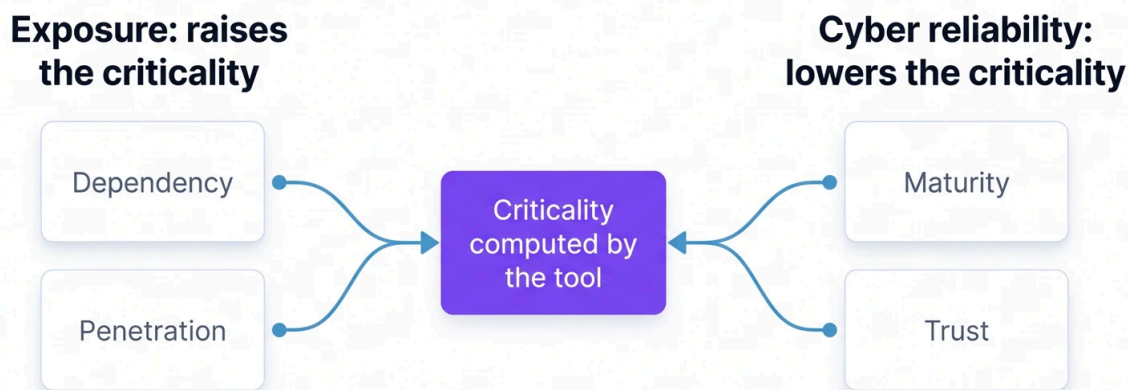

Prerequisites

- The domain of the subsidiary under review and the assets entered into CISO Assistant since session 2: the business assets and supporting assets, to be reused without ever recreating them.
- The session 5 work in the tool: the "4x4 risk matrix from EBIOS-RM" imported, and the study "Étude EBIOS RM MERIDIAN - [subsidiary under review] et [dependency from S6] - cycle 1", brackets filled in session 5, with its workshops 1 and 2 entered: framework, linked assets, baseline audit, six rated feared events, five RO/TO (risk origin / target objective) pairs of which three selected.
- The D5 file: the framing, the motivated risk origin / target objective pairs, the feared events rated in severity, and the group's scales, to be reused as they are.
- This morning's tutorial: the dangerousness map, the critical stakeholders, the structure of a strategic scenario and of an operational scenario.

What this lab handles, and what the tool can do

This lab extends into the tool the work done by hand this morning, in the EBIOS RM module opened yesterday. Yesterday, the study was created and its workshops 1 and 2 entered: framework, assets, baseline, feared events, RO/TO pairs. Today, workshops 3 and 4 of the same study open, those that carry the rated stakeholders, the strategic scenarios, the attack paths and the operational scenarios. This lab picks up that study, copying nothing over, and adds three families of objects to it: the ecosystem's stakeholders, the strategic scenarios and their attack paths, then a first operational scenario.

Two points on what the tool does, verified on the deployed version. First, it models the stakeholder with four rating criteria, in current value and in residual value: dependence and penetration (which measure exposure), maturity and trust (which measure cyber reliability). Second, it computes by itself the criticality of each stakeholder from these four ratings, following the guide's logic: exposure increases criticality, reliability reduces it. The result is displayed as a number, dependency multiplied by penetration, divided by maturity multiplied by trust, each rating running from 0 to 4. Dangerousness is therefore not to be computed by hand: it is justified through the four ratings, and the result is read. This is exactly the dangerousness map of Workshop 3, in the form of manipulable objects.

This lab is written as results to achieve and validation criteria, not as a series of clicks: at the end, the study must contain such and such an object, and that is what is verified on screen, whatever interface path was taken.

A word on the point of entering all this into the tool rather than onto a sheet. An ecosystem spreadsheet lives three weeks then dies in a shared folder. An EBIOS RM study entered into the tool, on the contrary, links each stakeholder to its ratings, each strategic scenario to its risk origin / target objective pair and to its feared event, each operational scenario to its attack path. Those links are what makes the work transmissible: session 7 will not start from scratch, it will open the study and take up its objects to rate and treat them. This work does not fill in an exercise, it builds a piece of the MERIDIAN file that will follow the group all the way to the final defense.

✓ Exercise 1: picking up the session 5 EBIOS RM study (5 minutes)

Open the study created in session 5, "Étude EBIOS RM MERIDIAN - [subsidiary under review] et [S6 dependency] - cycle 1", and check that its Workshops 1 and 2 reflect D5, without re-entering anything: D5 is authoritative. Complete in the study any missing or divergent object.

To produce: the study page whose counters show the subsidiary's assets, one audit, six feared events and five RO/TO pairs of which three retained, identical to D5.

✓ Exercise 2: entering the ecosystem as stakeholders (10 minutes)

Take up the studied object of the tutorial, the number one critical asset of the subsidiary under review, and identify its ecosystem from the session 2 mapping and from §3 and §6 of the subsidiary pack: at least four stakeholders, taken among the providers, the other subsidiaries and the clients that appear there. Create each one in the EBIOS RM module and give it a category among those of the tool.

To produce: at least four stakeholders attached to the study, each corresponding to an actor named in §3 or §6, none invented.

✓ Exercise 3: rating dangerousness and reading criticality (15 minutes)

For each stakeholder, fill in the four current rating criteria, dependency, penetration, maturity and trust, backing each rating with a fact from the subsidiary pack and not with an impression. Read the criticality the tool computes, spot the most critical stakeholder or stakeholders and tick "Selected" on each: they are the ones that will enter the strategic scenarios.

To produce: at least four stakeholders rated, each rating justified by one line backed by a fact from the pack, the criticality read for each, and the critical stakeholders ticked "Selected".

💡 The tool's criticality is not a truth fallen from the sky: it is the product of the four ratings entered. If the result is surprising, it is not the mathematics that should be contested, it is the ratings that should be re-examined and re-justified. It is the same reflex as with a weighted grid in session 3: the tool makes the deliberation transparent, it deliberates in no one's place.

✓ Exercise 4: creating two strategic scenarios and their attack paths (15 minutes)

Take two of the three RO/TO pairs retained in Workshop 2 and, for each, create a strategic scenario attached to the pair and to the focused feared event. Create in it at least one attack path going through a critical stakeholder of the previous exercise, attach that stakeholder and tick "Selected" on the path. Describe each path by

distinguishing the intermediate event, carried on the ecosystem, and the feared event, carried on the business asset; read the severity on the D5 scale.

To produce: two strategic scenarios, each with an attack path ticked "Selected" linked to a critical stakeholder, severity displayed from the feared event.

✓ Exercise 5: beginning Workshop 4 with an operational scenario (10 minutes)

Choose the most worrying attack path and create the operational scenario that corresponds to it: describe the sequence of elementary actions on the supporting assets, estimate its overall likelihood on the D5 scale (V1 to V4) and attach it to its attack path, ticked "Selected". The complete Workshop 4 is the substance of session 7; here, the first stone.

To produce: at least one operational scenario attached to an attack path, with its description of operating modes and its likelihood justified by the security baseline and its limits.
